WRAPBOOK

The Product Manager AI Fluency Matrix

A shared vocabulary for what AI fluency looks like in practice for product managers. Not a scorecard, but a conversation tool for setting direction and growing the craft.

What matters

The focus is on the impact you have with AI, not usage. Using AI is assumed and foundational. The core of product management hasn't changed: **high judgment, customer obsession, and problem-solving are still the whole game.** This is a map of how the best PMs amplify that foundation with AI, and where to grow next.

How to use the matrix

This is a conversation tool, not a scorecard. Assess where you land in each domain with real examples, compare with your manager, and set goals where it makes sense to grow. "Good" is a real bar; a PM hitting Good across most domains has genuinely changed how they work.

The Three Tiers

Good

AI is your default operating mode across your whole PM practice.

Great

AI has measurably changed the quality of your decisions and outputs, and you've built reusable systems that increase your and your team's efficiency.

Transformative

You think AI-first about team, department, and customer problems, building tools and proactively spotting where AI compounds your team's speed permanently.

DOMAIN	Good	Great	Transformative
Discovery & Research	You don't start solutioning without synthesizing across calls, tickets, and data with AI. This is just how you work, not something you do when you have extra time.	Your programmatic synthesis consistently surfaces gaps, contradictions, and blind spots. You discover problems before sales, customers, or internal teams do. You know what you don't know before you start solutioning.	Your discovery process is a reusable, programmatic team asset. You automatically surface assumption gaps in your own and others' work before anyone asks.
Iterative Development & Continuous Discovery	PRDs are iterative; you partner with eng, TPMs, and design before anything is finalized. Stakeholders aren't surprised at launch because they've been in the loop throughout. Prototyping is a regular tool, not a special event.	Your feedback loops are tight and structured. Prototypes change specs, and you can point to documented spec changes driven by customer or stakeholder input. Stakeholders co-shape the solution rather than review a finished doc.	You've changed how your team ships. Eng, design, and cross-functional partners have shifted how they expect to work with PMs because of what you modeled. The iterative loop is the team's default, and AI is what makes it sustainable at scale.
Data & Metrics	You use AI and natural-language querying to answer your own data questions in real time. You don't leave syncs with "I'll follow up," you pull the answer in the room.	You use AI to develop your measurement approach: generating metric options, identifying leading vs. lagging indicators, and designing how you'll track success before eng work starts. AI surfaces gaps in what you plan to measure.	You've built AI-powered metric frameworks or shared queries the team uses. You're changing how PMs think about measurement, surfacing patterns and problems proactively rather than waiting to be asked.
Communication & Alignment	AI drafts your first cut of every update; you edit and send, not write from scratch. You generate comms at the right altitude without a blank page. Leadership doesn't have to ask follow-up questions.	You programmatically generate comms at multiple altitudes from a single source doc: one input, three outputs. You prompt for counterarguments before presenting to leadership so objections are already addressed.	You've built comms templates or automation chains the team uses. Alignment happens faster across the team because of systems you created, not just your own good habits.
Systems & Automation	AI is woven into your daily and weekly rhythm. You're not doing manually what can be systematized, and your time reflects it.	You've built transferable systems (prompt libraries, automation chains, workflow templates) that work without you and improve over time. You can hand them off and they hold.	You proactively identify team P0s where AI is the right solution and ship tools to fix them. You treat internal leverage problems like product problems, and can point to something running, adopted, and saving real time.
AI Product Design	You own the quality bar on the AI features you're responsible for. Failure modes and human fallbacks are defined, not implied.	You write eval specs before dev starts: what good output looks like, how to test it, how to detect drift in production. You own quality end-to-end, not just at launch.	You've designed or led an eval process in production. You're the team's go-to on AI feature quality, raising the standard for how AI-powered features ship.

Illustrative examples of the same PM work at each level of fluency. These are generic scenarios, not real projects.

WRAPBOOK

DOMAIN	Good	Great	Transformative
Discovery & Research	Before a planning review, you use AI to synthesize dozens of customer calls, support tickets, and research docs in hours instead of a week, walking in with sourced themes and specific quotes, not vibes.	While synthesizing research, AI flags that nearly all your signal comes from one customer segment. You catch the blind spot before speccing, fill the gap with targeted calls, and the spec changes materially as a result.	You build an agent that flags recurring problems in your area across intake channels and pre-drafts a problem statement from existing research. It becomes how the team discovers problems, and other PMs find gaps they'd have missed.
Iterative Development & Continuous Discovery	You build a working prototype of a new flow in an afternoon and test it with real end users before writing a line of spec, catching a workflow mismatch and fixing it the same day.	Before speccing, you prototype and run a session with cross-functional stakeholders. One flags an edge case that would have forced a rebuild. You can point to the exact spec changes that came from that input, not assumptions.	Sprint kickoffs no longer start with a PRD handoff. Eng and design now expect to be in prototype reviews with customers. The team has cut a full phase from the old process and ships more confidently.
Data & Metrics	In a sync, someone asks for activation by segment. Instead of "I'll follow up," you run the query live and answer in 90 seconds. The meeting keeps moving.	Before a feature enters dev, you use AI to design the full measurement plan (metric options, leading vs. lagging indicators) and catch that two metrics can't be tracked without new instrumentation, in time to add it.	You create a shared query and prompt library that other PMs use. Questions that used to go to the data team are now self-served, and the team surfaces anomalies proactively instead of at quarterly review.
Communication & Alignment	Your weekly update is drafted by AI from rough notes in minutes; you edit and send. It goes out on time with zero "what's the status?" follow-ups from leadership.	Your review doc is auto-drafted from your team's updates. Before presenting, you prompt the AI to argue against your prioritization; it surfaces two objections you hadn't addressed, and you build responses in.	You build a weekly-update template other PMs adopt. Leadership alignment on those areas now happens in writing before meetings, not during them, and stakeholders always know where projects stand.
Systems & Automation	You automate your weekly prep: a scheduled task pulls open tickets, recent themes, and OKR status into a single brief every Monday. Ninety minutes becomes ten.	You build a prompt library tuned to your domain's constraints and use it across all your specs. When a new PM joins your area, the prompts go with them, productive in week one, not month one.	You spot that the whole team manually compiles summaries each week, and build an automation that pulls and formats them, saving hours a week and running without anyone thinking about it.
AI Product Design	A team is manually reconciling data across two systems in a spreadsheet. You build a lightweight AI-powered tool that pulls the data into one place, eliminating the context-switching.	You ship an automated tracker that replaces the spreadsheet entirely. Before dev you wrote an eval spec (what good output looks like, failure cases, how to measure accuracy in production) so eng knew what "good" meant before writing code.	That tool becomes the template for auditing other manual workflows: identify it, build detection, define the eval spec, own quality in production. Other PMs adopt the pattern across their domains.
