Stanley fatmax stud finder s300 manual

The Stanley Stud Sensor 300 is an electronic tool that detects the center of studs, joists, or live AC wires through common building materials like drywall. It uses signals to locate the stud centers and provides a visual display and audible tone once it's detected. The device has a marking channel for noting the stud center and edges on the wall. However, it won't detect objects in concrete, mortar, block, or brick work, carpeting, foil-faced materials, metallic surfaces, or ceramic tiles. It also can't locate non-ferrous or plastic objects like pipes. The tool requires a 9-volt battery (not included) to operate. Before using the Stud Sensor 300, read all instructions and do not remove any labels from the device. Wear safety goggles and protect your eyes. The device has various modes, including STUD Mode, METAL SCAN Mode, AC TRACKING Mode, and Self-Calibration Complete. To use the device, open the back door and connect the battery clip to the 9-volt battery. Close the door and ensure that the "Ready" icon appears on the LCD display. Hold the device flat against the surface, making firm contact, and press the activation button. A series of tones will sound, indicating that the device is calibrating. Once calibrated, move the device to a different location and try again. The device will detect studs and display their relative position on the screen. When it detects the center of a stud, an audible tone will sound, and the "Center" icon will appear on the LCD. Use the marking channel to note the stud center. If the device is not detecting studs, check that it's properly calibrated and that you're not moving it too quickly or directly over dense materials like metal or wet surfaces. The device can be turned off by releasing the activation button.
