## Concerta to vyvanse conversion

**Conversion methylphenidate to vyvanse. How much concerta is equal to vyvanse. Concerta dose equivalent to vyvanse. Concerta to vyvanse conversion reddit. 20 mg vyvanse to concerta conversion. Can you switch from concerta to vyvanse. Switching concerta to vyvanse. Concerta to vyvanse. Convert concerta to vyvanse.**

The ADHD Medication Converter is a medical tool designed to simplify medication management for healthcare professionals. It helps with starting, adjusting, or switching medications like Adderall to Vyvanse. The website and App are easy to use and tailored for clinicians' needs. Users input current and new medications along with their doses, and the calculator provides approximate dosing for the new medication. Additionally, by selecting a current medication on the App, users get further information such as starting and increasing dosage guidelines, maximum allowed doses, time to peak activity, and available dosing options. The tool also indicates which meds can be crushed and when the maximum dose has been exceeded. However, it's crucial for clinicians to note that conversions involve uncertainties due to individual variability, making clinical judgment and careful titration essential. Users must agree to terms of use acknowledging that this calculator is meant as a reference aid only and not a substitute for professional expertise. It also comes with disclaimers regarding accuracy and liability. Both Concerta and Vyvanse are long-lasting ADHD meds that differ from others like Ritalin. In this article, we compare their differences and similarities, as well as the side effects and dangers associated with each. Since both Concerta and Vyvanse are stimulants, they have very similar effects on the body. The main difference between the two medications is that Vyvanse works differently; it's a prodrug, which means it doesn't become active until your body processes it. Another key similarity is that both medications last for about 12 hours, making them great options for those who prefer to take medication just once a day. This can be especially helpful for children, as remembering multiple doses per day can be quite challenging. Concerta uses a unique system called the osmotic-controlled release oral delivery system (OROS) that ensures a steady flow of the drug throughout the day. However, it's worth noting that there are cheaper generic versions available, but these don't come with the OROS pump system and may not have the same effects as Concerta. This also means that the tablets must be swallowed whole and cannot be chewed or crushed. Doctors typically start by prescribing the lowest dose of Concerta possible and increase it only if needed. Concerta is approved for treating ADHD symptoms in people aged 6-65 years old, working by increasing norepinephrine and dopamine levels in the brain. Vyvanse has a different name in generic form: lisdexamfetamine. It's used to treat both ADHD and binge eating disorder in adults. The body breaks down Vyvanse into dextroamphetamine after ingestion, but exactly how it treats these conditions is not fully understood by doctors. Vyvanse comes in capsule or chewable tablet forms, with various strength options available for each. Doctors usually start patients on 30 mg once daily and can increase the dose as needed up to a maximum of 70 mg per day. A person with a history of heart conditions or glaucoma should avoid taking Concerta or Vyvanse, as these stimulants can cause significant health problems. Additionally, those who have mental health conditions may experience worsening symptoms while using either medication. It is crucial for individuals to consult their doctor before starting treatment with either Concerta or Vyvanse.
