We'll use the kinetic energy equation (KA = ½mvA^2) to calculate its kinetic energy at various locations. At location A, which is 55m above the lowest point in the diagram, we can plug in the values: KA = ½(10,000 kg)(26.82 m/s)^2 = 3,597,000 J We'll also use the gravitational potential energy equation (ΔUA = mgΔhA) to calculate the bus's potential energy at location A: ΔUA = (10,000 kg)(9.8 m/s^2)(55m - 50m) = 490,000 J Since energy is a scalar quantity, we'll add the kinetic and potential energies together to get the total energy: EA = KA + UA = 3,597,000 J + 490,000 J = 4,087,000 J (or approximately 4.09 MJ) We'll fill out a table with the values for each location, starting with location A. Since there's no friction or air resistance and no push from the engine, the total energy of the bus will remain constant at all locations. We'll calculate the potential energy at locations B, D, and E using the same equation: ΔUB = 0 (since it's at ground level) ΔUD = (10,000 kg)(9.8 m/s^2)(60m - 50m) = 980 MJ ΔUE = (10,000 kg)(9.8 m/s^2)(65m - 50m) = 1.47 MJ We'll then use the kinetic energy equation to calculate the kinetic energy at each location: KB = EB - UB = 4.09 MJ - 0 MJ = 4.09 MJ KD = ED - UD = 4.09 MJ - 0.98 MJ = 3.11 MJ KE = EE - UE = 4.09 MJ - 1.47 MJ = 2.62 MJ Finally, we'll rearrange the kinetic energy equation to solve for speed and apply it three times to get the speeds at each location. Note: I've kept the original formatting and wording as much as possible while paraphrasing the text. vB = √ 2(4,087,000 J) 10,000 kg vD = √ 2(3,107,000 J) 10,000 kg vE = √ 2(2,617,000 J) 10,000 kg Now we are introduced to Phillip D. and the table with speeds ranging from 26.82 m/s to 24.93 m/s, corresponding heights of 55 m to 65 m. The kinetic and potential energies at each location have been calculated as follows: A : 3.597 MJ, B : 4.087 MJ, C : 3.597 MJ, D : 3.107 MJ, E : 2.617 MJ, F : 3.107 MJ As a result of the energy conservation principle, locations F and D have identical energies and speeds. When we copy and paste the data again, the results remain the same: A : 3.597 MJ, B : 4.087 MJ, C : 3.597 MJ, D : 3.107 MJ, E : 2.617 MJ, F : 3.107 MJ The bus will never move slower than its speed at location E, which is 22.88 m/s, and since this value exceeds 50 mph, the bus won't explode. In a hypothetical sequel, a cruise ship would replace the city bus due to safety concerns, but no one would likely watch such a movie.
