This computer stopped working due to an inability to boot, presenting a constant amber power light. Diagnostic tests indicated issues with the motherboard (MB) or CPU, as swapping the power supply (PSU) did not resolve the problem. Given that it's out of warranty, purchasing new parts is considered. The user seeks advice from others who have experienced similar issues, hoping for assistance in fixing or repairing the computer. I initially had the manual and couldn't spot those crucial codes 1 and 2, but after re-examining it, they're clearly visible this time around. With that newfound understanding, my plan has shifted towards scrapping the current system and investing in a brand-new one instead. I appreciate all your input guys!
