

United
States
of
America

To Promote the Progress

of Science and Useful Arts

The Director

*of the United States Patent and Trademark Office has received
an application for a patent for a new and useful invention. The title
and description of the invention are enclosed. The requirements
of law have been complied with, and it has been determined that
a patent on the invention shall be granted under the law.*

Therefore, this United States

Patent

grants to the person(s) having title to this patent the right to exclude others from making, using, offering for sale, or selling the invention throughout the United States of America or importing the invention into the United States of America, and if the invention is a process, of the right to exclude others from using, offering for sale or selling throughout the United States of America, products made by that process, for the term set forth in 35 U.S.C. 154(a)(2) or (c)(1), subject to the payment of maintenance fees as provided by 35 U.S.C. 41(b). See the Maintenance Fee Notice on the inside of the cover.

Coke Moya Smead

ACTING DIRECTOR OF THE UNITED STATES PATENT AND TRADEMARK OFFICE

Maintenance Fee Notice

If the application for this patent was filed on or after December 12, 1980, maintenance fees are due three years and six months, seven years and six months, and eleven years and six months after the date of this grant, or within a grace period of six months thereafter upon payment of a surcharge as provided by law. The amount, number and timing of the maintenance fees required may be changed by law or regulation. Unless payment of the applicable maintenance fee is received in the United States Patent and Trademark Office on or before the date the fee is due or within a grace period of six months thereafter, the patent will expire as of the end of such grace period.

Patent Term Notice

If the application for this patent was filed on or after June 8, 1995, the term of this patent begins on the date on which this patent issues and ends twenty years from the filing date of the application or, if the application contains a specific reference to an earlier filed application or applications under 35 U.S.C. 120, 121, 365(c), or 386(c), twenty years from the filing date of the earliest such application (“the twenty-year term”), subject to the payment of maintenance fees as provided by 35 U.S.C. 41(b), and any extension as provided by 35 U.S.C. 154(b) or 156 or any disclaimer under 35 U.S.C. 253.

If this application was filed prior to June 8, 1995, the term of this patent begins on the date on which this patent issues and ends on the later of seventeen years from the date of the grant of this patent or the twenty-year term set forth above for patents resulting from applications filed on or after June 8, 1995, subject to the payment of maintenance fees as provided by 35 U.S.C. 41(b) and any extension as provided by 35 U.S.C. 156 or any disclaimer under 35 U.S.C. 253.

(57) **ABSTRACT**

Disclosed implementations provide executable models, such
as artificial intelligence models that can be owned, traded,
and used in various execution environments. By coupling a
model with a strictly defined interface definition, the model
can be executed in various execution environments that
support the interface. Coupling the model with a non-
fungible cryptographic token allows the model and other
components to be owned and traded as a unit. The tradeable
composite units have utility across multiple supported
execution environments, such as video game environments,
chat bot environments and financial trading environments.
Additionally, the interface allows for the creation of pipe-
lines and systems from multiple complementary composite
units.

INTEROPERABLE COMPOSITE DATA UNITS FOR USE IN DISTRIBUTED COMPUTING EXECUTION ENVIRONMENTS

BACKGROUND

Computing execution environments, such as distributed video game environments, bot networks, and complex financial transaction environments have become ubiquitous. In many such environments, participants can be represented as an object with privileges and characteristics. For example, in a video game environment, a player avatar may have specific capabilities, such as speed, agility, and strength. The capabilities associated with the player avatar can be stored within the execution environment. However, each environment has its own formats and protocols. Further, these environments must have a centralized trusted authority that is the keeper of the data. Accordingly, use of the objects must remain in the creating execution environment and activity in other environments does not, and cannot, affect the object. Further, the need for a trusted party prevents implementation of such objects on decentralized computing execution environments, such as blockchain networks and other distributed ledger technology (DLT).

BRIEF SUMMARY

Disclosed implementations provide executable models, such as artificial intelligence models that can be owned, traded, and used in various execution environments. By coupling a model with a strictly defined interface definition, the model can be executed in various execution environments that support the interface. Coupling the model with a non-fungible cryptographic token allows the model and other components to be owned and traded as a unit. The composite data structure representing the model is referred to as a “composite unit” herein. The tradeable composite units have utility across multiple supported execution environments, such as video game environments, chat bot environments and financial trading environments. Additionally, the interface allows for the creation of pipelines and systems from multiple complementary composite units.

An aspect of the invention is a method for creating a composite data structure recorded on non-transitory computer readable media for providing a computation model that can be implemented in multiple execution environments, the data structure comprising: a model module specifying model code that, when executed by a computer processor, causes computation on data in accordance with the computation model; an interface definition module including a pointer to an interface definition associated with the computation model; and a non-fungible token module including a pointer to a non-fungible token associated with the computation module, where the non-fungible token is stored on a decentralized ledger.

Another aspect of the invention is the use of the composite data structure within and execution environment.

Another aspect of the invention is a system including an execution environment for using the data structure.

BRIEF DESCRIPTION OF THE DRAWING

The foregoing summary, as well as the following detailed description of the invention, will be better understood when read in conjunction with the appended drawings. For the purpose of illustrating the invention, there are shown in the drawings various illustrative embodiments. It should be

2

understood, however, that the invention is not limited to the precise arrangements and instrumentalities shown. In the drawings:

FIG. 1 is a schematic representation of the structure of a composite unit in accordance with disclosed implementations.

FIG. 2 is an example of code for an interface definition in accordance with disclosed implementations.

FIG. 3-1 is a schematic illustration of linking between composite units and an input value matrix in accordance with disclosed implementations.

FIG. 3-2 is a continuation of FIG. 3-1 and is a schematic illustration of linking between composite units and an input value matrix in accordance with disclosed implementations.

FIG. 3-3 is a continuation of FIG. 3-1 and FIG. 3-2 and is a schematic illustration of linking between composite units and an input value matrix in accordance with disclosed implementations.

FIG. 4 is an example of a code snippet of the model code in accordance with disclosed implementations.

FIG. 5 is another example of a code snippet of the model code in accordance with disclosed implementations.

FIG. 6 is a table illustrating an input value matrix in accordance with disclosed implementations.

DETAILED DESCRIPTION

Certain terminology is used in the following description for convenience only and is not limiting. Unless specifically set forth herein, the terms “a,” “an” and “the” are not limited to one element but instead should be read as meaning “at least one.” The terminology includes the words noted above, derivatives thereof and words of similar import.

The composite units in accordance with disclosed implementations provide trade-ability, interoperability and composability of models, such as artificial intelligence that can be implemented in various execution environments and moved from one execution environment to another. By coupling an execution model with a strictly defined interface definition, the composite unit allows multiple execution environments to implement support for the interface and for other models to fit into that interface. The result is the ability to own and trade composite units that have utility across multiple supported execution environments. Additionally, the interface allows for the creation of pipelines and systems from multiple complementary composite units.

A composite unit in accordance with disclosed implementations includes 3 components:

Execution Model: a specification of executable code implementing the model (e.g., a content addressed URL where an executable code AI model is stored and accessible);

Interface Definition: a specification of inputs accepted by the model and outputs of the model (e.g., a content addressed URL where an interface definition for the relative model is stored and accessible).

Blockchain Reference: A pointer to a Non-Fungible Token (NFT) corresponding to the model and stored on a decentralized computing network, such as a blockchain or other distributed ledger technology.

FIG. 1 illustrates the architecture of a composite unit in accordance with disclosed implementations. Composite unit 100 includes content addressed model 102, interface specification 104, and token pointer 106 (which associates the composite unit 100 with an NFT stored on decentralized ledger 110. Note that elements 102, 104, and 106 are data elements stored on non transient computer-readable media

as a data structure. The elements can be linked in various manners, such as with pointers, by being stored in a single data structure, through relational tables, or the like. Also, the elements can store the corresponding data or code, or can otherwise specify the data or code through a URL or other address, a link, or the like. For example, content addressed model **102** can include the model code for executing the model or, as illustrated in FIG. 1, include an address to the storage location of the model code. Decentralized ledger **110** can be part of a decentralized environment such as a blockchain network. The NFT is a unique token that can be used to identify and represent ownership of composite unit **100**, regardless of the executing environment in which composite unit **100** is being used at the time.

As a simple example of composite unit **100**, consider the classic computer game PONG™. An example interface definition for a composite unit for the computer game PONG™ is shown in FIG. 2. As illustrated in FIG. 2, the input, from the most recent N (N=2 in this example) frames of game play are shown at **202** and **204**. The inputs include x and y positions of the ball, and each player's paddle, from which the following can be deduced:

Ball position, speed, and trajectory;

Opponents paddle position, speed, and trajectory; and

Player's own paddle position, speed, and trajectory.

The output of the interface in this example is the player's paddle movement instructions for the next frame, as shown at **206**. The x and y values will be added to the current player's paddle position.

By defining a strict interface for model inputs and outputs the models can be deployed across multiple environments that provide support for that interface. The constraints of standard PONG™ are very simple and the physics are linear, but this interface could be applied to multiple variants with different constraints and physics. By tweaking the number frames taken as input, models could be trained for a game variant with more complex constraints and non-linear physics. The disclosed implementations can be used to create a diverse ecosystem of competitive PONG™ tournaments where AI models are trained to compete across the field in different variants of the game. Disclosed implementations can be applied to more complex environments in gaming and beyond as described in examples below.

Composite units can be linked across execution environments (referred to as "arena's" herein) via an input value matrix which is a data structure containing a set of values that can be mapped to input variables within the arena and composite unit. This allows both consistency and flexibility in how the composite units are deployed by providing a single input reference but giving the arena developers the choice on how they are mapped. Arenas can refer to any environment the composite unit might interact with, examples include a level within a video game, an entire game, a trading bot, and/or a single interaction. "arena agents" are the code that executes the outputs of the composite unit.

FIG. 3-1, FIG. 3-2, and FIG. 3-3 illustrate multiple composite units, one for each arena, coupled to an input value matrix. Each composite unit, **300a**, **300b**, and **300c** in this example, has a corresponding arena agent **302a**, **302b**, and **302c**. Input value matrix **304** is coupled to each composite unit through the corresponding arena agent.

A very simple example input value matrix, in table form, is set forth below.

| | |
|---------|---|
| Value 1 | 5 |
| Value 2 | 2 |
| Value 3 | 6 |

With respect to the video games PONG™ and SPACE INVADERS™, application of the input value matrix might be as follows. In PONG™, an arena developer might want to add a constraint to the agent for maximum paddle speed, this can be achieved by mapping Value 3 in the input value matrix to the speed variable within the controller script, which can be part of model of the corresponding composite unit **100** (see FIG. 1). A snippet of an example of model code which controls movement of the paddle is illustrated in FIG. 4. The speed variable is indicated at **402**. In an example relating to SPACE INVADERS™, an arena developer might want to add a constraint to the agent for maximum speed of the space craft by mapping Value 3 to the input value for the variable speed, indicated at **502**, within the controller script shown in FIG. 5 (which is an example of a snippet for controlling space craft movement in the game).

The input value matrix described with respect to FIG. 3-1, FIG. 3-2, FIG. 3-3, FIG. 4 and FIG. 5 is a very simple example for illustrative purposes. FIG. 6 illustrates a more complex input value matrix **600** in accordance with disclosed embodiments. At least some of the variables in the input value matrix **600** represent attributes of a player entity in a video game. In the example of FIG. 6, a set of variables can be related to a category of attributes. For example, attributes **602** represent strength of the player entity with respect to the relevant arena, attributes **604** represent intelligence of the player entity with respect to the relevant arena, and attributes **606** represent agility of the player entity with respect to the relevant arena. Each set of values in input value matrix can be mapped to an array of variables in model code or each variable can be mapped to an individual variable in the model code. The input value matrix can be randomly generated and each game developer can designate/tag areas of the matrix as corresponding to specific skills. Tags can be associated with each area and game developers can leverage the tags created by previous developers to create a similar skill set for a similar game. Developers of different types of games may choose to create and or use a set of tags that is very different from a set of tags for a different game. Therefore, the input value matrix can be a set of values and associated TAG cloud(s) that can be used/grouped/tagged as desired. The game developer can decide which tags to use based on the type of game and desired play characteristics, but likely would want to be consistent with other similar games.

As noted above, the composite unit in accordance with disclosed implementations can be applied to video games. Disclosed implementations of a gaming platform and protocol example are described in greater detail below. The platform allows users to mint game player entities (referred to simply as "players" below) and upgrade their statistics, earn, buy, and sell them as NFTs within the ecosystem. The model code incorporates machine learning to create a "brain" that can change and adapt within, and as a result of, gameplay.

The protocol and platform allow multiple games to be created by developers to interact with players. Different players can have different levels of various relevant skills (such as strength, speed, intelligence, . . .). A player may be an interactive intelligent non-player character (NPC) in a game with human backed players. An NPC is character or other entity in a game that is not controlled by the person(s)

5

playing the game. A player can be defined by 3 parts, the base “frame”, a “form” defining the player’s aesthetic and attributes (for example, the frame and form can be in the form of the input value matrix defined above), and a trainable “brain” (for example in the form of the executable model described above. A user can create new players by minting a new NFT Pack including these components with default attributes. Some frames, forms and/or brains will contain rare attributes or may start from a higher level in their potential meaning, for example, that the corresponding player is a faster learner who take less time to reach the pinnacle of certain skills.

To play a game, a frame, form, and brain are selected and linked to one another. With gameplay each component will be modified in unique ways. The combination of frame, form and brain impact the learning model and can produce an extremely large set of decision making processes and combinations in the specific machine learning model storage for the player (i.e., the brain). Simply attaching a “more advanced” brain or “more capable” form to a frame might not immediately result in a superior player because a brain that has been trained to use a form with certain attributes will need to relearn when combined with a form with different attributes or with different values for those attributes. Even two frames with forms and brains with identical attributes might also develop totally different training in the brain model based on game play. This allows for an enormous universe of unique “personalities” to develop.

This model of separating attributes and attribute values, which can be attached and detached from a frame, allows users to design the ultimate strategy by combining unique parts of the player from different frames, forms and brains. Significantly, this structure allows a user to choose a form for a specific arena or a brain for a specific task or strategy or when facing a specific opponent. Each form or brain can be categorized, for example, as 1 of 5 types; Defective, Common, Rare, Epic, and Legendary. The Players can be defined using a .yaml file that holds the attributes and is stored using IPFS. YAML is a serialization language that is often used as a format for configuration files as a replacement for languages like JSON. IPFS is a well-known peer-to-peer hypermedia protocol. YAML is only one example of a file structure/format that could be used to store data defining a player and attributes. As a result of this configuration, “memories” are immutable, decentralized, and can be linked specifically to an NFT.

A frame includes a set of universal attribute values assigned at minting. The values can start low but could be upgraded by completing tasks in the platform and/or purchasing boosts with the platform currency. For example, the frame attribute values can correspond to:

- Strength;
- Fitness;
- Speed;
- Dexterity;
- Intelligence;
- Charisma;
- Perception;
- Luck; and/or
- Size

Forms can be game-specific and can have attribute values providing additional skills or attributes, to modify skills and attributes, for a specific task, such as a game against a specific opponent. In order to enter an arena, an arena specific form can be required to be attached to the frame. This allows a frame to participate in multiple arenas if it has multiple forms.

6

Forms can also contain multipliers of frame stats that might be useful for a specific arena. These can be randomly assigned and can include rare attributes. Once a form is minted, games can upgrade skill levels internally through mapping multipliers or the like.

Brains can be defined as frames, i.e. a memory address associated with an NFT and storing the code for executing a learning model. Brains can be used with various forms. However, a new form may require the brain to learn how to use the modified attributes and attribute values specified therein. Brains also have attributes which can boost the attached frame and might be more useful to a specific arena(s). Frames can contain multiple memories which store the training for a specific learning model and form combination to thereby allow training for several combinations for a specific arena.

In order for a brain to learn, it needs to be trained through activity, e.g., game play. Training can be accomplished in a “gym” platform. A “gym”, as used herein, can be a GPU-powered machine learning model trainer. The model is influenced by the attributes associated with the player NFT. As the learning model of the brain uses a neural network, the specific outcomes of training a specific player are unique. Players are able to model their attributes by training at a gym, which in turn makes their AI better at playing the game. Each player can have an .onnx file that is updated each time they train at the gym. ONNX is an open format built to represent machine learning models. Training at the gym can be a process similar to mining cryptocurrency, where GPUs are used to train the unique brain of your NFT. The protocol can provide an incentive to those who host the gym as the users of the gym can be required to pay for gym usage. During a gym session a user will be able to see their player improve, by monitoring the attributed through a file viewer for example, and be able to end the session once their decided outcome is achieved.

Users can connect to a game using their web3 wallet. The user then selects a player which is a combination of frame, form, brain and memory. Multiple players can be selected to create a team in the case of team play such as football. Two teams are required for a match/game. The game starts and the players are loaded, the game checks to ensure that NFT associated with the combination of frame, form, brain and memory is owned by the user when they enter the arena. The two sides compete to score enough winning points/goals in a specific time period.

The output of this result can be stored on a distributed ledger, such as a blockchain network against the record of the relevant NFTs. This enables an ecosystem of economic incentives and activities to develop around the players and the outcomes of Games. Game, player, and team stats can be displayed in various manners. Users can view an inventory of their frames, forms and brains as well as the makeup of their players and how the stats impact the players. A user interface can be provided to allow players to be modified by attaching a combinations of frames/forms/brains. Users could wager on the outcome of games or rent a team to play a match or borrow a player to upgrade their team.

The platform includes a distributed ledger having a native token to be used for the payments noted herein. The token can be mined using a liquidity mining event. Once a user holds a native token, the user can use the native token to mine (or buy) a pack of a frame/form/brain combination. Packs will have a random chance of spawning a rare component of each. Mining can be based on a fair distribution curve, and a minimum stake can be required to mine a pack. The time it takes to mine can be reduced based on a

user's staked amount. This allows early or strong supporters to benefit as well as later or smaller supporters to participate.

To make the game fair even for smaller participants, an increase in stake need not necessarily increase your individual chance of getting a rare attribute upon minting of an NFT. However, larger stakeholders could be able to mine more packs in the same amount of time with respect to smaller stakeholders. Packs can be released in editions and, over time, editions can contain new attributes as the models evolve or some editions may contain limited runs. However, because the performance of a player is determined by its training and experience even a "low" spec character has a chance of developing a winning capability/strategy. The native token can also be used for the payments between providers of GPUs to gyms and users of those gyms. Native tokens can also be used to purchase players from other users, to buy access to an arena, or to purchase cosmetic items or loot boxes for players.

Various known technology platforms and protocols can be used in connection with the disclosed implementations. The NFTs can be minted using the ERC-1155 token standard. Such NFTs are specifically for gaming and enable more efficient trade and transfer on the Ethereum network than is possible through ERC-721 alternatives.

CHAINLINK™ RNG (Random Number Generator) and VRF (Verified Randomness Function) can be used to provide randomness both in game mechanics (such as a coin toss for where the ball starts) and in minting mechanics for rare attributes associated with the NFTs. The Chainlink oracle network can also be used to enable the NFTs to have dynamic attributes which build up during game play. SYLO protocol, an ecosystem made up of digital consumer wallet software, applications, infrastructure & developer tools, can be used for in game chat and marketplace chat as well as for NFT wallets. IPFS can be used for storing the memories associated with an NFT and ensuring the brain in a game is using the correct NFT. UNITY can be used for the game engine.

The specific examples described above relate primarily to video games. However, the disclosed implementations can be applied to various applications and the "player" entity could be, for example, a chat bot (to give an individual personality to an online friend), a personal assistant that is truly personal, and/or a trading bot which acts on behalf of its owner or its community to accomplish transactions in accordance with a dynamic trading strategy. Any task that could be completed by an intelligent automated agent could be accomplished using the disclosed implementations.

It will be appreciated by those skilled in the art that changes could be made to the disclosed implementations without departing from the broad inventive concept thereof. It is understood, therefore, that this invention is not limited to the disclosed implementations, but it is intended to cover modifications within the spirit and scope of the present invention as defined by the appended claims.

What is claimed:

1. A non-transitory computer readable media for providing a plurality of computation models that are each implemented in a respective arena environment, the data structure including software modules recorded thereon and, for each computation model, the modules comprising:

- a model module specifying an AI model that, when executed by a computer processor, causes computation on data to accomplish a corresponding task;
- an interface definition module including a pointer to an interface definition associated with the computation

model that is used by a corresponding one of the respective arenas to communicate with the model code; and

an arena agent coupling each model module to a data structure containing a set of values that are mapped to input variables within each of the respective arena environments, whereby the data structure links the agent with other agents across the arena environments; a token module including a pointer to a unique token associated with the computation module.

2. The non-transitory computer readable media of claim 1, wherein the interface definition specifies a finite set of inputs and outputs for the computation model.

3. The non-transitory computer readable media of claim 2, wherein the task is at least one of a chat bot task, a personal assistant task, a financial transaction task and/or a task related to activity of an entity in a video game.

4. The non-transitory computer readable media of claim 1, wherein the token is a non-fungible token stored on a decentralized ledger.

5. The data structure of claim 4, further comprising an input value matrix which holds multiple values that are mapped to input variables within the model code and wherein the multiple values of the input value matrix are used to train the learning module.

6. The non-transitory computer readable media of claim 1, wherein the values are changed as a result of activity of the AI model.

7. A method for creating a composite data structure recorded on non-transitory computer readable media for providing a plurality of computation models that are each implemented in a respective arena environment, the method comprising:

providing a model module specifying model code that, when executed by a computer processor, causes computation on data in accordance with the computation model;

providing an interface definition module including a pointer to an interface definition associated with the computation model that is used by a corresponding one of the respective arenas to communicate with the model code; and

an arena agent coupling each model module to a data structure containing a set of values that are mapped to input variables within each of the respective arena environments, whereby the data structure links the agent with other agents across the arena environments; linking the computation model with a non-fungible token stored on a decentralized ledger.

8. The method of claim 7, wherein the interface definition specifies a finite set of inputs and outputs for the computation model.

9. The method of claim 8, wherein the computation model represents activity of an entity in a video game.

10. The method of claim 7, wherein the model module includes the model code.

11. The method of claim 7, wherein the model code includes a learning module.

12. The method of claim 11, wherein the learning module is an artificial intelligence model.

13. The method of claim 11, further comprising providing an input value matrix which holds multiple values that are mapped to input variables within the model code and training the learning module with the multiple values of the input value matrix.

14. The method of claim **7**, further comprising providing an input value matrix which holds multiple values that are mapped to input variables within the model code.

15. The method of claim **7**, wherein the interface definition specifies actions that can be taken by the entity. 5

16. The method of claim **15**, wherein the values represent attributes of the entity.

17. The method of claim **16**, wherein the values are changed as a result of entity activity.
