## Abstract

This study evaluates Munsit, CNTXT AI's Arabic text-to-speech (TTS) system, against two commercial TTS systems (ElevenLabs, MiniMax) and professionally recorded human speech, using a blind, randomized listening test. For each of 30 test items, native Arabic-speaking evaluators heard four recordings of the same text — one from each system, with system identity withheld — and rated every recording independently on an overall-quality scale reported on the conventional 1–5 range (ITU-T P.800/P.808 convention) and on three sub-criteria (dialect fidelity, pronunciation accuracy, naturalness). A panel of 352 evaluators produced 3,602 valid ratings across 369 test sessions, spanning Modern Standard Arabic (MSA), Saudi Arabic, and Emirati Arabic. On the 1–5 scale, Munsit and the human reference scored within statistical noise of each other (4.27 vs. 4.30; paired difference  $-0.03$ , 95% CI  $[-0.08, 0.02]$ ), and both scored significantly higher than ElevenLabs (4.02) and MiniMax (2.92). As a secondary, item-level comparison, we also computed the share of evaluations in which each system received the single highest rating: Munsit was top-rated in 53.1% of evaluations (95% CI  $[50.0, 56.1]$ ), against 25.7% for the human reference, 17.2% for ElevenLabs, and 4.0% for MiniMax. Munsit's margin over every comparator on this measure was statistically significant overall and within the MSA and Saudi subsets ( $p < 0.001$ , cluster bootstrap); within the Emirati subset Munsit led numerically, but the smaller subsample ( $n = 32$  sessions) did not establish a statistically reliable difference; a follow-up Emirati panel is planned. **We interpret these results as evidence that Munsit has reached rating parity with professionally recorded human speech**, with a small but statistically detectable edge in how often it is rated the single best option among the four, for the dialects tested.

## 1. Introduction

Mean Opinion Score testing (ITU-T P.800, P.808) asks listeners to rate speech on a fixed scale, typically 1 to 5. This works well when systems differ widely in quality. It works poorly once systems are all good: ratings crowd near the top of the scale, and two systems a listener clearly prefers in practice can end up with statistically identical mean scores. This study reports ratings on the standard 1–5 scale as its primary outcome, following ITU-T convention. But because our systems are close in quality, we also compute a secondary, item-level measure directly from the same ratings: for each test item, which of the four recordings received the single highest rating. This top-rated share is conceptually related to comparative methods such as Comparative Mean Opinion Score (CMOS) protocols and public benchmarks such as TTS Arena, which ask listeners to choose between systems directly rather than rate each one in isolation. Unlike those methods, it is derived from the rating data itself rather than from a separate forced-choice task. Reporting both measures lets us check whether a real difference is being masked by scale compression in the primary ratings.

## 2. Methods

### 2.1 Experimental Design

Each test item presented four recordings of an identical Arabic-language text segment, spoken in a matched gender voice, generated respectively by Munsit, ElevenLabs, MiniMax, and a professional human speaker. System identity was withheld from evaluators, and the assignment of systems to presentation positions was re-randomized independently for every item. Each evaluation session comprised 10 items drawn from a fixed item bank of 30 items (10 per dialect),

spanning two use-case categories (conversational-assistant and documentary-style narration). For each item, evaluators rated every one of the four recordings independently on a 1–10 overall-quality scale (reported on the standard 1–5 scale; Section 2.4) and on three sub-criteria; dialect fidelity, pronunciation accuracy, and naturalness; using 5-point scales. There was no forced choice between systems: each recording was scored on its own merits. The 1–5 quality rating is the primary outcome measure, reported in Section 3.4. As a secondary, derived measure, we also record which of the four recordings received the single highest rating on each item; this top-rated share is reported first, in Sections 3.1–3.3, because it is the more sensitive measure near the quality ceiling (Section 1).

## 2.2 Participants

The evaluator panel comprised 352 unique native Arabic speakers: 251 evaluating Modern Standard Arabic content, 76 Saudi natives evaluating Saudi Arabic content, and 25 Emiratis evaluating Emirati Arabic content. Evaluator dialect matched the dialect of the assigned content in 100% of evaluations, satisfying the native-listener requirement for dialect-fidelity judgment.

## 2.3 Data Quality Assurance

Two independent screening procedures were applied prior to analysis. First, one item in every session was shown twice; once early and once near the end. Sessions where the evaluator gave inconsistent answers on that repeated item were excluded, following the crowdsourced-evaluation quality-control practice recommended by ITU-T P.808. Second, a platform-level validity screen excluded sessions from accounts whose personal identity and nationality could not be validated. The dataset analyzed in this report — 369 sessions and 3,602 evaluations — reflects both screens and is the full analysis population. No further exclusions were applied.

## 2.4 Statistical Analysis

Overall-quality ratings were collected on a 1–10 scale and converted to the conventional 1–5 range for reporting via a simple linear transformation; the three sub-criteria were collected natively on 5-point scales. A recording is counted as top-rated on an item when it received the single highest rating among the four recordings. When two or more recordings tied for the highest rating, the recording presented first among those tied was counted as top-rated; because the assignment of systems to presentation positions was re-randomized for every item, this rule favors no system. Each evaluation therefore contributed exactly one top-rated outcome.

Evaluations within a session are not independent; each session reflects repeated judgments from the same evaluator. To account for this, all inferential statistics use a cluster bootstrap that resamples whole sessions, not individual evaluations, as the unit of resampling (5,000 resamples with replacement). 95% confidence intervals for top-rated shares and quality ratings are the 2.5th and 97.5th percentiles of the resulting bootstrap distributions. To compare Munsit with another system, we compute the difference between the two systems on each of the 5,000 bootstrap resamples — the difference in top-rated share, or, for quality ratings, the average per-evaluation rating difference — which yields a distribution of plausible values for the true difference. When that distribution lies almost entirely on one side of zero, the observed difference is unlikely to be a chance result; the reported two-sided p-value is computed from the share of resamples falling on the opposite side of zero (twice the smaller tail proportion). For the top-rated measure, the natural reference point is 25%: if all four systems were of equal quality, each would receive the single

highest rating about one time in four, so a share meaningfully above 25% indicates a genuine preference. Inter-rater reliability was assessed using pairwise percent agreement and Krippendorff's alpha computed on the interval-scaled quality ratings, with items (dialect  $\times$  item identifier  $\times$  system) as the unit of analysis.

### 3. Results

#### 3.1 Top-Rated Share, Overall

As introduced in Section 2.1, each item's four recordings were rated independently, and the recording with the single highest rating on that item is counted as top-rated. Across the full analysis population, Munsit was top-rated in 53.1% of evaluations (95% CI [50.0, 56.1]), compared with 25.7% for the human reference, 17.2% for ElevenLabs, and 4.0% for MiniMax. The difference in top-rated share between Munsit and the human reference was 21.9–32.7 percentage points (95% CI), a difference that excludes zero and is therefore statistically significant ( $p < 0.001$ ).

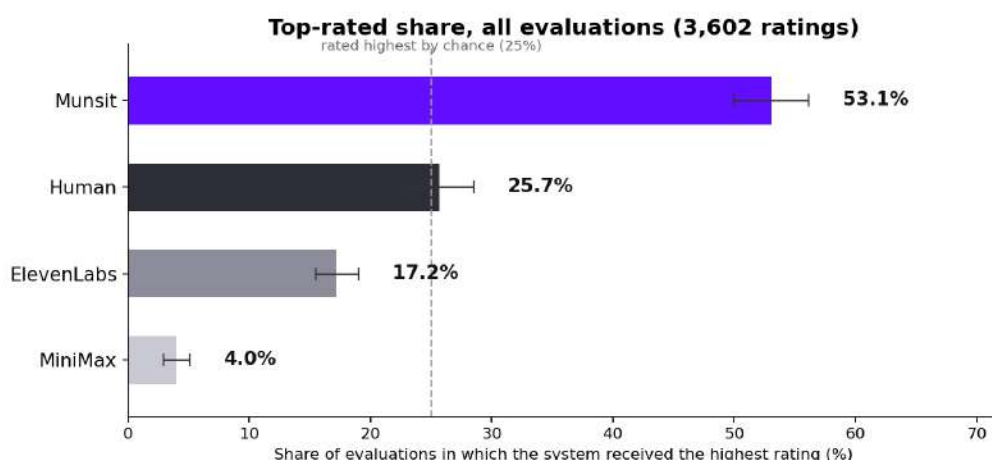

Figure 1. Top-rated share by system, all dialects combined (369 sessions, 3,602 evaluations). Error bars denote 95% cluster-bootstrap confidence intervals; the dashed reference line indicates the 25% share expected if all four systems were rated highest equally often.

Table 1. Top-rated outcomes, all dialects combined.

| System            | n (top-rated) | Top-rated share | 95% CI (bootstrap) | Difference vs. Munsit, 95% CI | p       |
|-------------------|---------------|-----------------|--------------------|-------------------------------|---------|
| Munsit            | 1912          | 53.1%           | [50.0, 56.1]       | —                             | —       |
| Human (reference) | 926           | 25.7%           | [23.0, 28.5]       | [21.9, 32.7] pp               | < 0.001 |
| ElevenLabs        | 620           | 17.2%           | [15.5, 19.0]       | [31.7, 39.8] pp               | < 0.001 |
| MiniMax           | 144           | 4.0%            | [2.9, 5.1]         | [45.4, 52.6] pp               | < 0.001 |

#### 3.2 Top-Rated Share by Dialect

Munsit's margin over the human reference was statistically significant in both the MSA subset (55.9% vs. 25.7%; difference 23.6–36.6 percentage points,  $p < 0.001$ ) and the Saudi subset (48.1% vs. 22.1%; difference 15.2–36.4

percentage points,  $p < 0.001$ ). The Emirati subset tells a different story, but not because the result reverses: Munsit's top-rated share was still numerically higher than the human reference's (43.1% vs. 35.2%). The subset comprised only 32 sessions, and the interval on the difference ( $[-14.6, 30.6]$  percentage points,  $p = 0.49$ ) spans zero. Munsit led numerically in this subset, but the smaller sample did not establish a statistically reliable difference; a follow-up Emirati panel is planned to resolve this comparison (Section 6). Munsit's advantage over the two commercial systems, by contrast, held up robustly across all three dialects: every comparison against ElevenLabs and MiniMax reached statistical significance at  $p < 0.001$ , including within the smaller Emirati subsample (ElevenLabs  $p = 0.0008$ ; MiniMax  $p < 0.001$ ).

Figure 2. Top-rated share by dialect and system, with 95% cluster-bootstrap confidence intervals. The Emirati subsample (32 sessions) yields correspondingly wider intervals.

Table 2. Modern Standard Arabic (255 sessions, 2,501 evaluations).

| System            | n (top-rated) | Top-rated share | 95% CI (bootstrap) | Difference vs. Munsit, 95% CI | p         |
|-------------------|---------------|-----------------|--------------------|-------------------------------|-----------|
| <b>Munsit</b>     | <b>1398</b>   | <b>55.9%</b>    | [52.3, 59.4]       | —                             | —         |
| Human (reference) | 643           | 25.7%           | [22.6, 29.0]       | [23.6, 36.6] pp               | $< 0.001$ |
| ElevenLabs        | 431           | 17.2%           | [15.3, 19.3]       | [33.8, 43.3] pp               | $< 0.001$ |
| MiniMax           | 29            | 1.2%            | [0.5, 1.9]         | [50.9, 58.5] pp               | $< 0.001$ |

Table 3. Saudi Arabic (82 sessions, 797 evaluations).

| System            | n (top-rated) | Top-rated share | 95% CI (bootstrap) | Difference vs. Munsit, 95% CI | p         |
|-------------------|---------------|-----------------|--------------------|-------------------------------|-----------|
| <b>Munsit</b>     | <b>383</b>    | <b>48.1%</b>    | [41.3, 54.9]       | —                             | —         |
| Human (reference) | 176           | 22.1%           | [16.9, 27.7]       | [15.2, 36.4] pp               | $< 0.001$ |
| ElevenLabs        | 150           | 18.8%           | [15.0, 22.8]       | [20.0, 38.5] pp               | $< 0.001$ |
| MiniMax           | 88            | 11.0%           | [8.0, 14.4]        | [28.1, 45.8] pp               | $< 0.001$ |

Table 4. Emirati Arabic (32 sessions, 304 evaluations); underpowered subsample.

| System            | n (top-rated) | Top-rated share | 95% CI (bootstrap) | Difference vs. Munsit, 95% CI | p         |
|-------------------|---------------|-----------------|--------------------|-------------------------------|-----------|
| <b>Munsit</b>     | <b>131</b>    | <b>43.1%</b>    | [30.1, 56.8]       | —                             | —         |
| Human (reference) | 107           | 35.2%           | [23.6, 47.0]       | $[-14.6, 30.6]$ pp            | 0.49      |
| ElevenLabs        | 39            | 12.8%           | [6.1, 21.0]        | [12.5, 48.6] pp               | $< 0.001$ |
| MiniMax           | 27            | 8.9%            | [4.1, 14.1]        | [17.9, 51.3] pp               | $< 0.001$ |

### 3.3 Item-Level Consistency

Each of the 30 items was rated independently by a large number of raters; more than 250 for MSA items, about 80 for Saudi items, and about 30 for Emirati items. This makes it possible to check Munsit's top-rated share at the level of individual items, not just in aggregate. Munsit's top-rated share exceeded the 25% chance level (one-sided binomial test,  $\alpha = 0.05$ ) on 26 of the 30 items, and it was the most frequently top-rated recording on 25 of the 30. This item-level consistency shows that Munsit's aggregate top-rated share is not driven by a handful of unusual items.

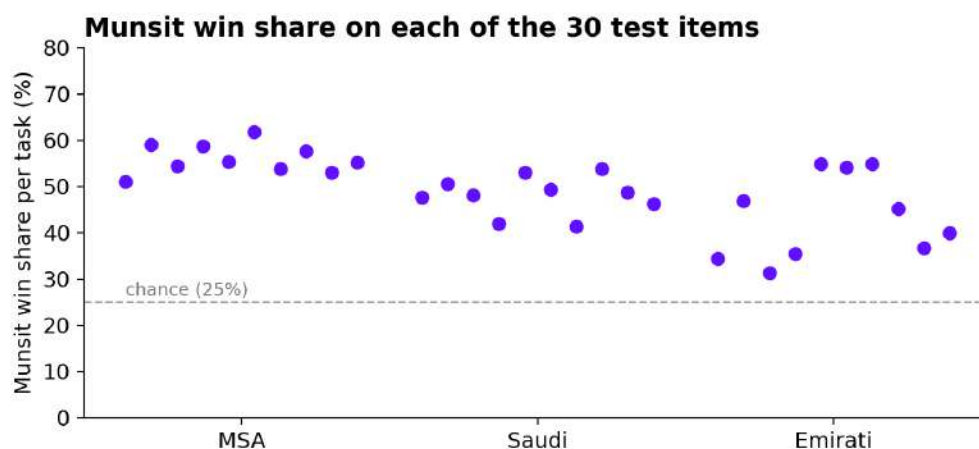

Figure 3. Munsit's top-rated share on each of the 30 evaluation items, grouped by dialect. The dashed line denotes the chance level (25%).

### 3.4 Overall Quality Ratings (1–5 Scale)

On the standard 1–5 quality scale, Munsit and the human reference scored within statistical noise of each other (4.27 vs. 4.30; paired difference  $-0.03$ , 95% CI  $[-0.08, 0.02]$ , an interval that includes zero). Both scored well above ElevenLabs (4.02) and MiniMax (2.92). The same pattern held across all three sub-criteria (each already collected on a native 1–5 scale): Munsit and the human reference differed by no more than 0.04 points on dialect fidelity, pronunciation accuracy, and naturalness, while ElevenLabs trailed by roughly 0.3–0.4 points and MiniMax by roughly 1.7–1.8 points. This is the ceiling effect from Section 1 in action: Munsit and the human reference rate the same on the 1–5 scale, yet Munsit is still the single highest-rated recording more often (Section 3.1). Averaged ratings and the top-rated share are two views of the same underlying data; the average smooths over item-by-item detail that the top-rated share preserves, which is why the two can tell slightly different stories near the top of the scale.

Table 5. Mean quality ratings and 95% cluster-bootstrap confidence intervals. The 1–5 rating is the primary reported score, for comparability with the conventional 5-point MOS convention (ITU-T P.800/P.808); it is not an independently collected P.800 MOS.

| System     | Overall rating (1-5), 95% CI | Dialect fidelity (1-5) | Pronunciation (1-5) | Naturalness (1-5) |
|------------|------------------------------|------------------------|---------------------|-------------------|
| Munsit     | 4.27 [4.21, 4.32]            | 4.10                   | 4.09                | 4.04              |
| Human      | 4.30 [4.24, 4.35]            | 4.13                   | 4.05                | 4.01              |
| ElevenLabs | 4.02 [3.96, 4.08]            | 3.82                   | 3.73                | 3.65              |
| MiniMax    | 2.92 [2.84, 3.00]            | 2.42                   | 2.40                | 2.23              |

Figure 4. Average quality ratings (1-5 scale) by system and dialect, with 95% confidence intervals.

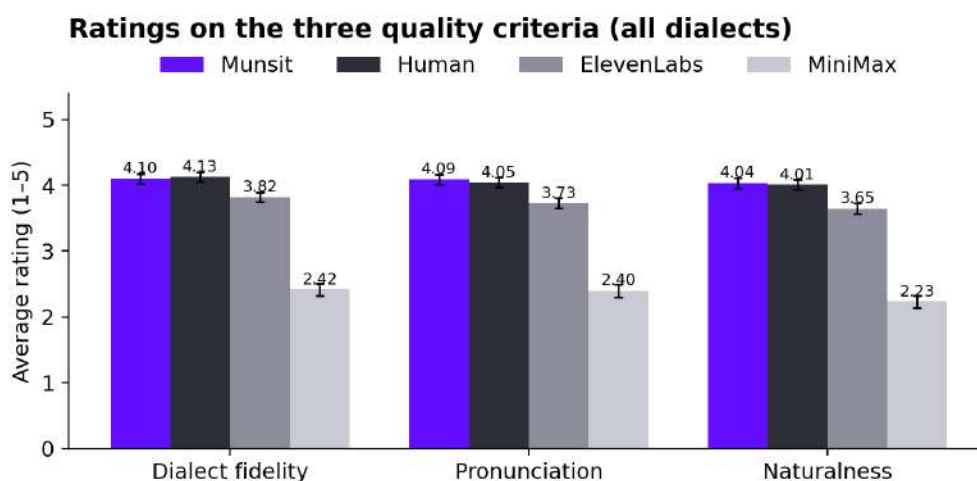

Figure 5. Mean ratings on the three quality sub-criteria, all dialects combined, with 95% confidence intervals.

### 3.5 Inter-Rater Reliability

Inter-rater consistency was assessed using three complementary measures. The first, pairwise percent agreement, captures how often two evaluators of the same item identified the same recording as best: 39.9% overall (40.7% for MSA, 32.5% for Saudi, 33.4% for Emirati), well above the 25% expected by chance across four systems. The second, Krippendorff's alpha, measures agreement on the quality ratings after correcting for chance. It was 0.49 for MSA, a typical value for subjective listening tests, and 0.06 for the Saudi and Emirati subsets, which were judged by fewer raters per item and involve inherently more subjective dialect judgments. The conclusion to draw from this measure is that the MSA ratings are reproducible across raters, whereas chance-corrected agreement in the Saudi and Emirati subsets is minimal, and their subgroup-level ratings should accordingly be interpreted with greater caution. The third, Fleiss' kappa, a chance-corrected measure of agreement on the top-rated outcome, was near zero in all three subsets. This reflects the well-documented 'kappa paradox': when most raters lean in the same direction, kappa approaches zero even though raw agreement remains high. Taken together, agreement is clearly above chance, and the item-level consistency in Section 3.3 provides the strongest evidence of reliability under this design.

## 4. Can a TTS Model Really Outrank Human Recordings?

The most counter-intuitive finding — human speech placing second to a synthetic system — deserves direct scrutiny, and the design anticipated it. Evaluators could not know which recording was human: systems were anonymized, order was re-randomized every item, and all four read identical text in the same gender voice, so nothing but the audio itself could drive the rating. The consistency check then removed submissions with unstable judgments before any analysis. If raters had been careless or biased, the pattern of results would look arbitrary; instead it is internally coherent in ways that are hard to fake.

Three such patterns stand out. First, the human reference was not rated poorly — 4.30 out of 5 overall and 4.01–4.13 across the three sub-criteria — and on MSA it is nearly tied with Munsit (4.40 vs. 4.39), exactly where studio-recorded formal Arabic should be strongest. Second, the gap opens precisely on dialectal content, where consistent, authentic dialect realization is hardest for voice talent to sustain across long recording sessions and where a model trained on curated dialectal speech is most advantaged. Third, the result replicates the published trend: recent literature (e.g., human-fooling-rate studies presented at Interspeech 2025) shows top TTS systems are now regularly preferred over recordings of the same content, because synthesis delivers studio-consistent prosody with no fatigue, session variance, or disfluencies. **The correct reading is not that Munsit is 'better than humans' in general; it is that Munsit has reached the human-parity regime:** blind listeners, given every tool to detect the machine, rated it the top choice more often than the human recording.

## 5. Limitations

Per-evaluation quality scores were available for the full analysis population, so the primary and secondary outcome measures reported here come from an identical dataset. The Emirati subsample (32 sessions) was underpowered to resolve the Munsit-versus-human comparison at the effect size seen in the other two dialects; we estimate roughly 100 sessions would be needed to reach comparable statistical power. Evaluator demographics beyond native-dialect matching — age, gender — and playback-environment controls, such as a headphone-use check, were not recorded. This falls short of full conformance with ITU-T P.808 panel-documentation recommendations. The human reference reflects one specific set of professional voice talents and recording sessions, not an upper bound on achievable human speech quality. The commercial comparator systems reflect their publicly available configurations during the data-collection period (May–June 2026) and are subject to change by their providers.

## 6. Future Work

Planned extensions to this evaluation program address the limitations above directly. The Emirati evaluation subsample will be expanded to a minimum of 100 sessions to achieve adequate statistical power. Evaluator demographic metadata and playback-condition verification will be collected in line with ITU-T P.808 panel-documentation recommendations. The evaluation will be repeated on a recurring cadence so that results remain current, covering both the latest Munsit checkpoints and the commercial comparator systems as their providers update them. Finally, the human reference will be broadened beyond a single set of voice talents and recording sessions to better represent the range of professional human speech.
